The use of opioids for recreational purposes also frequently leads to tolerance and other withdrawal effects, which may make recreational use unappealing for some opioid users. Effects The effects of opioids are a combination of various effects. There are many classes of drugs that have similar, or identical effects to opioids. Two types of effects that are commonly associated with opioids are their analgesic and euphoriant effects. Opioid analgesics work by binding to opioid receptors located in the central nervous system and receptors in the peripheral nervous system, causing a decrease in the perception of pain. There are many different classes of opioid analgesics, and these are typically classified based on their chemical structure. There are also opioids that induce a euphoric effect similar to other euphoriant drugs, although the exact mechanism by which these drugs produce euphoric effects are still not well understood. Psychological effects Many drugs that cause euphoric effects are also known to produce psychological effects. Although opioids have been shown to induce both stimulant-like effects and sedation, it is still unclear whether this is due to one class of drugs activating both the dopamine and the norepinephrine systems, or whether the effects are due to specific drugs. A study conducted in the 1980s found that opioids produced a similar effect to amphetamines, including the upregulation of norepinephrine receptors. This indicates that the drugs may activate the norepinephrine system, and produce similar effects in the brain. Other studies have found that although opioids cause an increase in dopamine and norepinephrine release, this effect does not occur to the same extent as stimulants, and other neurotransmitters may be responsible for the effect of opioids. This is supported by studies showing that opioid agonists are more potent stimulants than are opioid antagonists. It has also been shown that opioids can produce effects similar to amphetamines, such as increased reaction time and decreased short-term memory. Effects in opioid-naïve subjects The acute effects of opioids are sometimes described as "mind-altering" or "psychedelic" effects. In particular, opioid analgesics that are low-potency are often described as producing relatively mild effects that are not associated with these terms. The acute effects of opioids vary greatly from person to person. Some opioids, including morphine and heroin, are addictive, and they can lead to tolerance and dependence if taken chronically. These effects are less likely to occur in people who have no history of opioid use. Most studies of the 82157476af
